Introduction

What is different from other algorithms ?

- Low fragmentation.
- Mitigated performances on its own.
- Highly depends on the complementary strategies used with this algorithm.
- Really challenging approach.

- The idea is to manage a contiguous memory block of size n with n a power of two.
- The block can be given to the user as is or divided into two sub-blocks.
- The two sub-blocks are called buddies (each one is the buddy of the other).
- The logic is recursive and each sub-block can be given to the user or divided as well into two 2 sub-block, etc.
- Each block's size is therefore a power of two.
- You have to define a minimum size for the blocks.

Layouts

Management

- User does a malloc of size s .
- Compute the first power of two greater than or equal to s : $s2p$.
- Of course $s2p$ is greater or equal to the chosen minimum size.
- From there, find the smallest block possible of size at least $s2p$ in the tree.
- If the free block found is at least 2 times greater than $s2p$, divide it into two sub-block (the division is done recursively) until the sub-block size is as small as possible and still fits $s2p$.

- Mark the block as free.
- If the buddy of the block is also available, merge them to create a larger block.
- The merge is done recursively until it is not possible anymore.

Example

Step 1

Start with an initial block of size 1024 bytes.

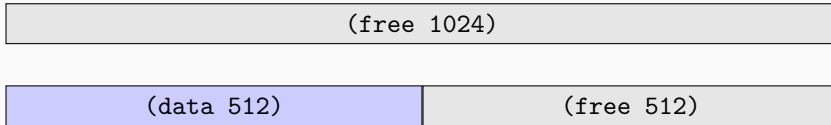

(free 1024)

Step 2

Allocation of 512 bytes:

- Split the block in two blocks of 512 bytes and use the first one.

Step 3

Allocation of 64 bytes:

- Split the free block of 512 bytes into two blocks of 256 bytes.
- Split the first block of 256 bytes into two blocks of 128 bytes.
- Split the first block of 128 into two blocks of 64 bytes and use the first one.

Step 4

Allocation of 120 bytes:

- The rounding power of two is 128 bytes.
- Use the already available block of 128 bytes.

| | | | | |
|-----|----|----|-----|-----|
| 512 | 64 | 64 | 128 | 256 |
|-----|----|----|-----|-----|

| | | | | |
|-----|----|----|-----|-----|
| 512 | 64 | 64 | 128 | 256 |
|-----|----|----|-----|-----|

Step 5

Allocation of 500 bytes:

- The rounding power of two is 512 bytes.
- There is no block large enough: allocation is not possible.
- Would have to create a new binary buddy (not in this example).

| | | | | |
|-----|----|----|-----|-----|
| 512 | 64 | 64 | 128 | 256 |
|-----|----|----|-----|-----|

Step 6

Free the block of 512 bytes:

- Mark the block as free.
- The buddy of the block is not free, the merge is not possible.

Step 7

Free the block of 64 bytes:

- Mark the block as free.
- Its buddy is also free: merge them into a free block of 128 bytes.
- The buddy of the new 128 bytes block is not free, the merge is not possible.

Step 8

Free the block of 128 bytes:

- Mark the block as free.
- Its buddy is free: merge them into a block of 256 bytes.
- The buddy of the new 256 bytes block is free: merge them into a block of 512 bytes.
- The buddy of the new 512 bytes block is free: merge them into a block of 1024 bytes.

| | | | |
|-----|-----|-----|-----|
| 512 | 128 | 128 | 256 |
|-----|-----|-----|-----|

| | | | |
|-----|-----|-----|-----|
| 512 | 128 | 128 | 256 |
|-----|-----|-----|-----|

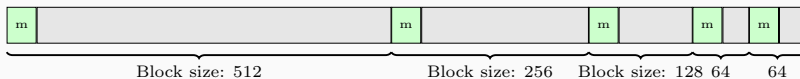

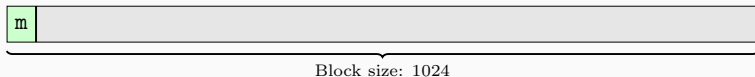

| | | |
|-----|-----|-----|
| 512 | 256 | 256 |
|-----|-----|-----|

| | |
|-----|-----|
| 512 | 512 |
|-----|-----|

At the beginning of each block you need some metadata, with at least:

- The block status (allocated / free)
- The block size

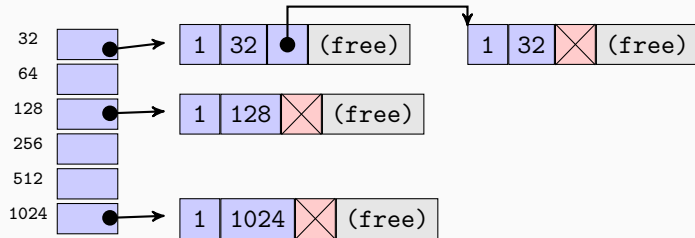

Start by reading the metadata on the left (first block):

- If the block is not available, move the pointer from block's size bytes to check the next block.
- If the block is of the right size you just need to mark it as used.
- If the block is available but too big, it needs to be split:
 - Update its metadata (reduce block size).
 - Create new metadata for the buddy issued by the division.
- The buddy of a block can be easily accessed with the formula:
 - $\text{block_addr} \wedge \text{block_size}$

Note: With the metadata, a block of size n (n a power of two) can fit for an allocation of size $n - \text{sizeof}(\text{metadatas})$.

- Allocation is very slow, while freeing a block is fast.
- It is almost necessary to use a data structure to keep track of the free blocks.
- Various data structures might be used: sized free-lists, binary trees...

Example using sized free-lists

Conclusion

- Division of the blocks.
- Low fragmentation.
- Hard to implement.
